Vellore Institute of Technology
(Deemed to be University under section 3 of UGC Act, 1956)

Course Code: BCSE308P

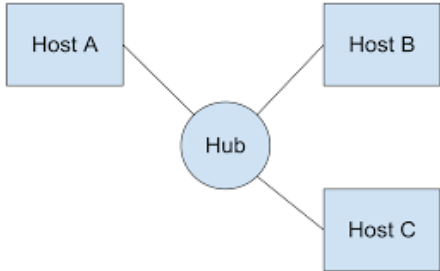

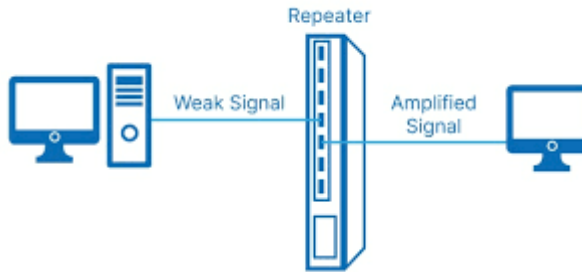

Course Name: Computer Networks Lab

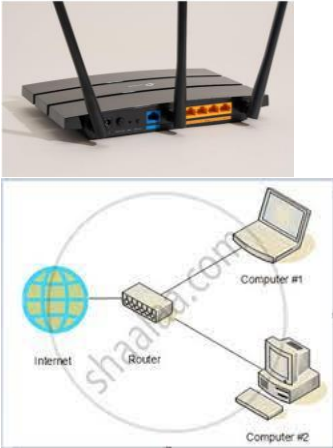

Assessment – 1

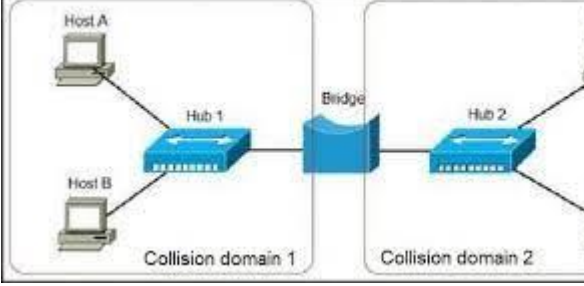

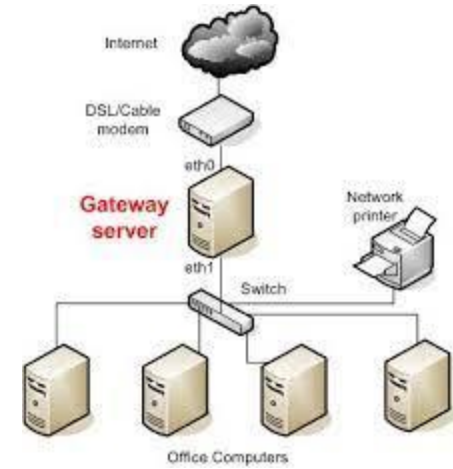

Name: Shivam Dave

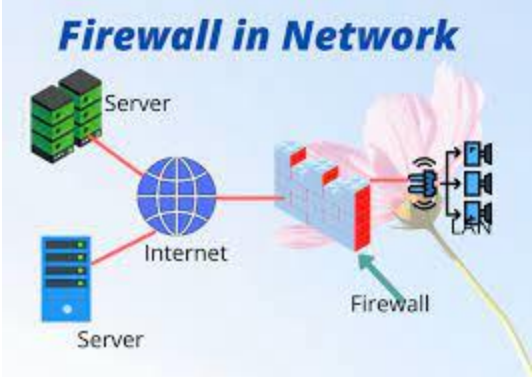

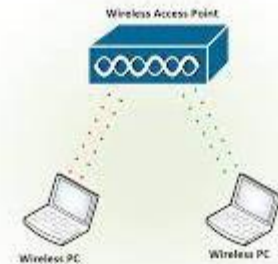

Reg. No.: 21BCB0107

Basic Networking Devices

Device Name	Fundamental Characteristics	Layer	Image
Hub	The main purpose of a hub is to connect all present network devices together on a predefined internal network. Hub is a device consisting of multiple ports that accept ethernet connections from network devices.	Layer 1 or the physical layer	 
Repeater	A repeater is a powerful network hardware device that regenerates an incoming signal from the sender before retransmitting it to the receiver. It is also known as a signal booster, and it helps in extending the coverage area of networks. The Incoming data can be in optical, wireless or electrical signals	It operates in OSI layer 1	

Switch	<p>Now, a switch is very similar to a hub. It also has multiple ports that accept the Ethernet connections from various network devices present. But unlike our hub, a switch is the intelligent one. A switch can learn the physical addresses of the devices that are actually connected to it, and then it stores these physical addresses called MAC addresses in its table. So whenever a data packet is sent to a switch, it's only directed to the intended destination port, unlike a hub where a hub will just rebroadcast the data to every port.</p>	<p>It operates in the second layer i.e. Data link layer</p>	
Router	<p>It serves two primary functions: managing traffic between these networks by forwarding data packets to their intended IP addresses, and allowing multiple devices to use the same Internet connection.</p>	<p>Routers are networking devices operating at layer 3 or a network layer of the OSI model</p>	

Network bridges	<p>Bridges are used to connect two or more hosts or network segments together. The basic role of bridges in network architecture is storing and forwarding frames between the different segments that the bridge connects. They use hardware Media Access Control (MAC) addresses for transferring frames. By looking at the MAC address of the devices connected to each segment, bridges can forward the data or block it from crossing. Bridges can also be used to connect two physical LANs into a larger logical LAN.</p>	<p>Bridges work only at the Physical and Data Link layers of the OSI model.</p>	 <p>The diagram illustrates a network bridge connecting two separate collision domains. On the left, 'Collision domain 1' contains 'Host A' and 'Host B' connected to 'Hub 1'. On the right, 'Collision domain 2' contains an unnamed host connected to 'Hub 2'. A 'Bridge' device is positioned between Hub 1 and Hub 2, facilitating communication between the two domains.</p>
Gateway	<p>Gateways normally work at the Transport and Session layers of the OSI model. At the Transport layer and above, there are numerous protocols and standards from different vendors; gateways are used to deal with them.</p>	<p>The gateway also operates at the data link layer (Layer 2) of</p>	 <p>The diagram shows a 'Gateway server' acting as a bridge between a local network and the 'Internet'. The Internet is represented by a cloud icon. A 'DSL/Cable modem' connects the Internet to the Gateway server via an 'eth0' interface. The Gateway server has an 'eth1' interface connected to a 'Switch'. This switch is then connected to a 'Network printer' and four 'Office Computers'.</p>

		the OSI network model.	
Firewall	A firewall is a network security device, either hardware or software-based, which monitors all incoming and outgoing traffic and based on a defined set of security rules it accepts, rejects or drops that specific traffic.	Firewalls typically work on the network layer, the transport layer.	
Wireless access point	Wireless access points (WAPs) consist of a transmitter and receiver (transceiver) device used to create a wireless LAN (WLAN). Access points typically are separate network devices with a built-in antenna, transmitter and adapter. APs use the wireless infrastructure network mode to provide a connection point between WLANs and a wired Ethernet LAN.	An Access Point is a Layer 2 device and therefore works on Layers 1 and 2.	

Modem	<p>Modems (modulators-demodulators) are used to transmit digital signals over analog telephone lines. Thus, digital signals are converted by the modem into analog signals of different frequencies and transmitted to a modem at the receiving location. The receiving modem performs the reverse transformation and provides a digital output to a device connected to a modem, usually a computer.</p>	<p>Modems also operate on Datalink layer</p>	 <p>The diagram illustrates the operation of a modem. It shows a computer on the left connected to a modem in the center. A green square wave, labeled 'Digital signal', represents the data being sent from the computer to the modem. The modem is then connected to a telephone line, which is represented by a green sine wave, labeled 'Analog signal'. The telephone line leads to a blue cloud, representing the network. An inset image in the top left corner shows a physical modem device.</p>

Q2) Basic Networking Commands

1)Ping Command

Uses:

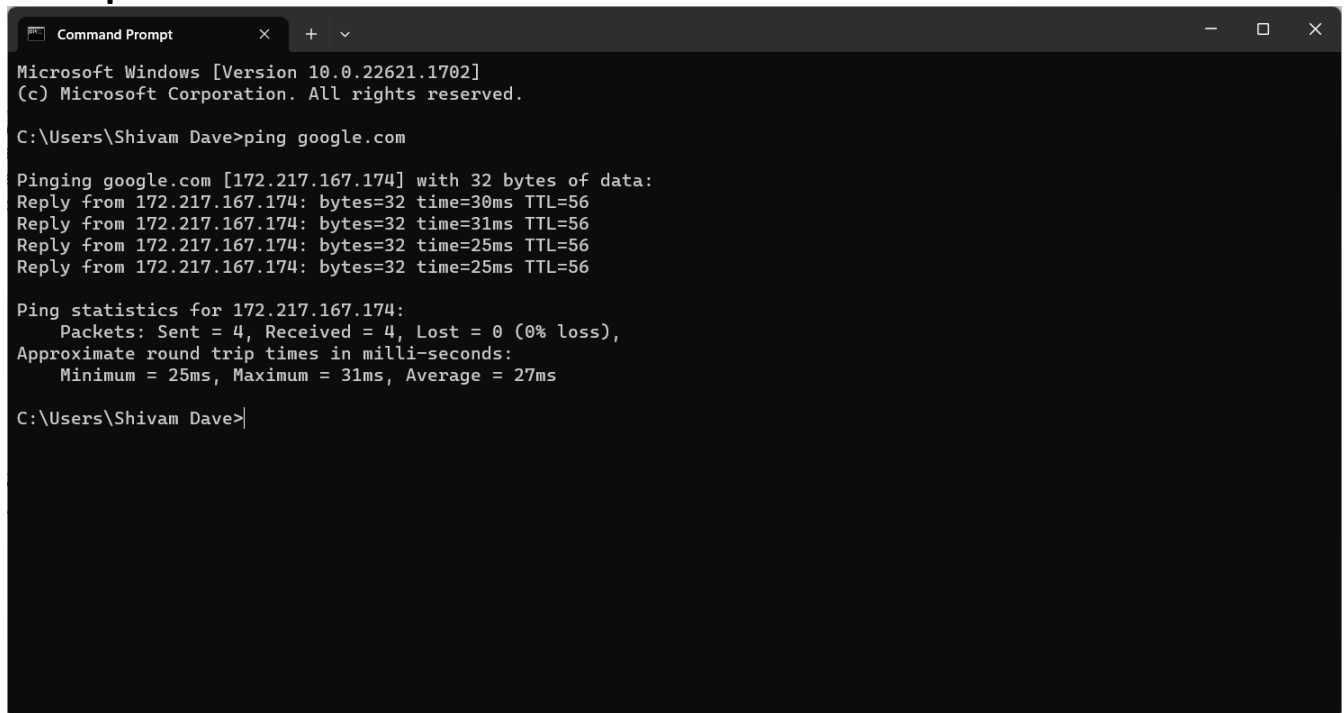

The ping command is one of the most often used networking utilities for detecting devices on a network and for troubleshooting network problems.

Syntax:

The general format is ping hostname or ping IPaddress.

```
ping google.com
```

Output:

```
Microsoft Windows [Version 10.0.22621.1702]
(c) Microsoft Corporation. All rights reserved.

C:\Users\Shivam Dave>ping google.com

Pinging google.com [172.217.167.174] with 32 bytes of data:
Reply from 172.217.167.174: bytes=32 time=30ms TTL=56
Reply from 172.217.167.174: bytes=32 time=31ms TTL=56
Reply from 172.217.167.174: bytes=32 time=25ms TTL=56
Reply from 172.217.167.174: bytes=32 time=25ms TTL=56

Ping statistics for 172.217.167.174:
    Packets: Sent = 4, Received = 4, Lost = 0 (0% loss),
    Approximate round trip times in milli-seconds:
        Minimum = 25ms, Maximum = 31ms, Average = 27ms

C:\Users\Shivam Dave>
```

2)ipconfig Command

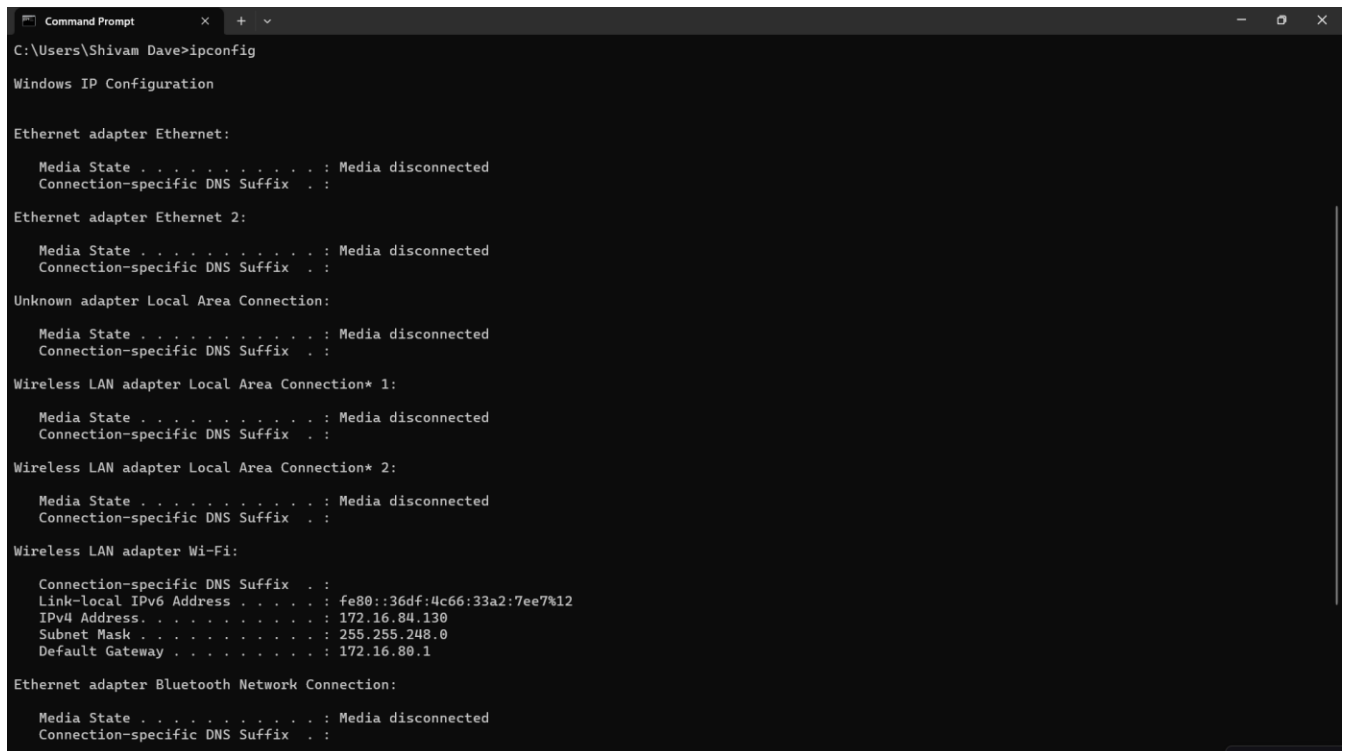

Uses:

Another indispensable and frequently used utility that is used for finding network information about your local machine like IP addresses, DNS addresses etc

Syntax:

ipconfig /parameter_name.

Output:

```
Command Prompt
C:\Users\Shivam Dave>ipconfig

Windows IP Configuration

Ethernet adapter Ethernet:

    Media State . . . . . : Media disconnected
    Connection-specific DNS Suffix  . :

Ethernet adapter Ethernet 2:

    Media State . . . . . : Media disconnected
    Connection-specific DNS Suffix  . :

Unknown adapter Local Area Connection:

    Media State . . . . . : Media disconnected
    Connection-specific DNS Suffix  . :

Wireless LAN adapter Local Area Connection* 1:

    Media State . . . . . : Media disconnected
    Connection-specific DNS Suffix  . :

Wireless LAN adapter Local Area Connection* 2:

    Media State . . . . . : Media disconnected
    Connection-specific DNS Suffix  . :

Wireless LAN adapter Wi-Fi:

    Connection-specific DNS Suffix  . :
    Link-Local IPv6 Address . . . . . : fe80::36df:4c66:33a2:7ee7%12
    IPv4 Address. . . . . : 172.16.84.130
    Subnet Mask . . . . . : 255.255.248.0
    Default Gateway . . . . . : 172.16.80.1

Ethernet adapter Bluetooth Network Connection:

    Media State . . . . . : Media disconnected
    Connection-specific DNS Suffix  . :
```

3)Hostname Command

Uses:

A very simple command that displays the host name of your machine. This is much quicker than going to the control panel>system route.

Syntax:

hostname

Output:

```
C:\Users\Shivam Dave>hostname
LAPTOP-69UQJ8VE
C:\Users\Shivam Dave>
```

4) getmac Command

Uses:

Another very simple command that shows the MAC address of your network interfaces

Syntax: getmac - Find MAC Address of your Local Computer

Output:

```
C:\Users\Shivam Dave>getmac

Physical Address    Transport Name
=====
00-FF-16-54-E7-32   Media disconnected
N/A                 Media disconnected
E0-70-EA-CE-14-10   Media disconnected
A8-93-4A-03-4C-B9   \Device\NPF{A95F714D-3CEA-45C4-AABB-6CB466527124}
A8-93-4A-03-4C-BA   Media disconnected

C:\Users\Shivam Dave>
```

5)Nslookup command

Uses:

main use of nslookup is for troubleshooting DNS related problems. Nslookup can be use in interactive and non-interactive mode.

To use in interactive mode type nslookup at the command line and hit return. We should get an nslookup command prompt.

Syntax: nslookup [option]

Output:

```
C:\Users\Shivam Dave>nslookup
Default Server:  UnKnown
Address:  172.16.80.1
```

```
> |
```

6) Netstat

Uses:

Netstat displays a variety of statistics about a computers active TCP/IP connection.

Netstat command displays various network related information such as network connections, routing tables, interface statistics, multicast memberships etc.,

Syntax:

netstat -a

Output:

```
> netstat
Server: Unknown
Address: 172.16.80.1
*** Unknown can't find netstat: Non-existent domain
> |
```

7.Route:

Uses:

The route command displays the computers routing table.

A typical computer, with a single network interface, connected to a LAN, with a router is fairly simple and generally doesn't pose any network problems.

Syntax:

route

Output:

```

Command Prompt
C:\Users\Shivam Dave>route

Manipulates network routing tables.

ROUTE [-f] [-p] [-4|-6] command [destination]
      [MASK netmask] [gateway] [METRIC metric] [IF interface]

-f          Clears the routing tables of all gateway entries. If this is
            used in conjunction with one of the commands, the tables are
            cleared prior to running the command.

-p          When used with the ADD command, makes a route persistent across
            boots of the system. By default, routes are not preserved
            when the system is restarted. Ignored for all other commands,
            which always affect the appropriate persistent routes.

-4          Force using IPv4.

-6          Force using IPv6.

command     One of these:
            PRINT      Prints a route
            ADD        Adds a route
            DELETE     Deletes a route
            CHANGE     Modifies an existing route

destination Specifies the host.
MASK          Specifies that the next parameter is the 'netmask' value.
netmask       Specifies a subnet mask value for this route entry.
            If not specified, it defaults to 255.255.255.255.
gateway       Specifies gateway.
interface     the interface number for the specified route.
METRIC        specifies the metric, ie. cost for the destination.

All symbolic names used for destination are looked up in the network database
file NETWORKS. The symbolic names for gateway are looked up in the host name
database file HOSTS.

If the command is PRINT or DELETE. Destination or gateway can be a wildcard,
(wildcard is specified as a star '*'), or the gateway argument may be omitted.

If Dest contains a * or ?, it is treated as a shell pattern, and only
matching destination routes are printed. The '*' matches any string,

Command Prompt

All symbolic names used for destination are looked up in the network database
file NETWORKS. The symbolic names for gateway are looked up in the host name
database file HOSTS.

If the command is PRINT or DELETE. Destination or gateway can be a wildcard,
(wildcard is specified as a star '*'), or the gateway argument may be omitted.

If Dest contains a * or ?, it is treated as a shell pattern, and only
matching destination routes are printed. The '*' matches any string,
and '?' matches any one char. Examples: 157.*.1, 157.*, 127.*, *224*.

Pattern match is only allowed in PRINT command.

Diagnostic Notes:
  Invalid MASK generates an error, that is when (DEST & MASK) != DEST.
  Example> route ADD 157.0.0.0 MASK 155.0.0.0 157.55.80.1 IF 1
  The route addition failed: The specified mask parameter is invalid. (Destination & Mask) != Destination.

Examples:

> route PRINT
> route PRINT -4
> route PRINT -6
> route PRINT 157*      .... Only prints those matching 157*

> route ADD 157.0.0.0 MASK 255.0.0.0 157.55.80.1 METRIC 3 IF 2
  destination^      ^mask      ^gateway      metric^      ^
                                Interface^

  If IF is not given, it tries to find the best interface for a given
  gateway.
> route ADD 3ffe::/32 3ffe::1

> route CHANGE 157.0.0.0 MASK 255.0.0.0 157.55.80.5 METRIC 2 IF 2

  CHANGE is used to modify gateway and/or metric only.

> route DELETE 157.0.0.0
> route DELETE 3ffe::/32

C:\Users\Shivam Dave>

```

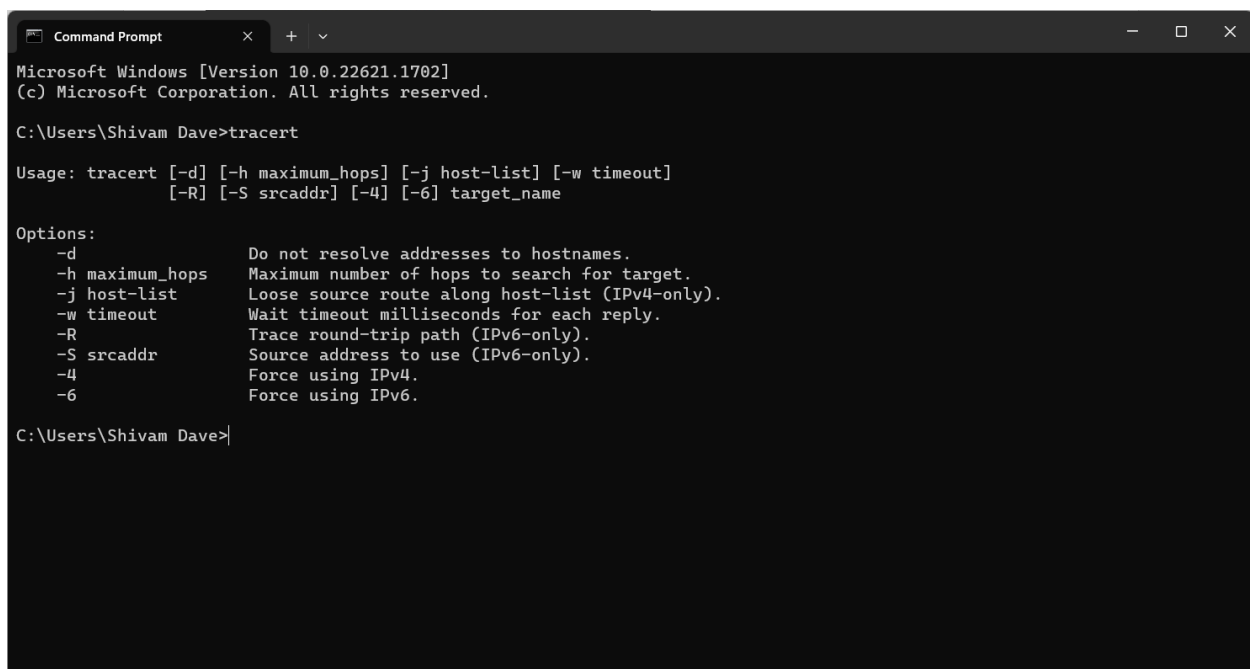

8.Tracert:

Uses:

The tracert command displays a list of all the routers that a packet has to go through to get from the computer where tracert is run to any other computer on the internet.

Syntax:

tracert [-d]

Output:

```

Command Prompt
Microsoft Windows [Version 10.0.22621.1702]
(c) Microsoft Corporation. All rights reserved.

C:\Users\Shivam Dave>tracert

Usage: tracert [-d] [-h maximum_hops] [-j host-list] [-w timeout]
              [-R] [-S srcaddr] [-4] [-6] target_name

Options:
  -d                Do not resolve addresses to hostnames.
  -h maximum_hops  Maximum number of hops to search for target.
  -j host-list      Loose source route along host-list (IPv4-only).
  -w timeout        Wait timeout milliseconds for each reply.
  -R               Trace round-trip path (IPv6-only).
  -S srcaddr        Source address to use (IPv6-only).
  -4               Force using IPv4.
  -6               Force using IPv6.

C:\Users\Shivam Dave>

```

9. tcpdump**Uses:**

tcpdump is a packet analyzer that is launched from the command line. It can be used to analyze network traffic by intercepting and displaying packets that are being created or received by the computer it's running on.

Syntax: tcpdump

10.telnet

Uses:

TELNET is commonly used by terminal emulation programs that allow you to log into a remote host. However, TELNET can also be used for terminal-to-terminal communication and interprocess communication. The **telnet** command is used to create a remote connection with a system over a TCP/IP network. It allows us to administrate other systems by the terminal. We can run a program to conduct administration.

Syntax: telnet hostname/IP address.

Q3)Code for finding the Class of the Network

```
#include<bits/stdc++.h>
using namespace std;
char Findclass(char cls[])
{
    char ans[4]; //to store the first octet in a particular character array
    int i=0;
    // for(int x=0;x<12;x++)
    // {
    //     if(cls[i]=='.')
    //     {
    //         ans[i]=cls[i];
    //         i++;
    //     }
    //     else
    //     {
    //         i--;
    //     }

    while(cls[i]!='.')
    {
        ans[i]=cls[i];
        i++;
    }
    i--;
    int j=0,k=1;
    while(i>=0)
    {
        j=j+(cls[i]-'0')*k;
        k=k*10;
        i--;
    }
    if( j>=0 && j<=127)
    {
        return 'A'; //class a
    }
    else if(j>127 and j<=191)
    {
        return 'B'; //class b
    }
    else if(j>191 and j<=223)
    {

```

```

        return 'C';//class c
    }
    else if(j>223 and j<=239)
    {
        return 'D';//class d
    }
    else if(j>239 and j<=255)
    {
        return 'E';//class e
    }
}
int main()
{
    cout<<"Enter ip address:";
    char cls[12];
    cin>>cls;
    char ip=Findclass(cls);
    cout<<"Given IP address belongs to the class: "<<ip;
}

```

OUTPUT:

```

> cd "c:\Users\Shivam Dave\Desktop\SEM 5\Computer Networks\" ;
($?) { .\Findclass }
Enter ip address:192.129.230.142
Given IP address belongs to the class: C
PS C:\Users\Shivam Dave\Desktop\SEM 5\Computer Networks>

```

```

> cd "c:\Users\Shivam Dave\Desktop\SEM 5\Computer Networks\" ; if ($?) {
($?) { .\Findclass }
Enter ip address:243.120.320.123
Given IP address belongs to the class: E
PS C:\Users\Shivam Dave\Desktop\SEM 5\Computer Networks>

```
